Passwords are encrypted, and decryption key is your password, if use wrong password it gives error and doesn't decrypt anything.

Source: PM Me.

Wow inv :> nice job <3..

pming you now for the source, i'll take a look on it :PP

Regards,
oneil

Its ok.. you need to test your programs first also, but not just for them working but "try" to break it..
le: enter wrong info, use it in the wrong manner, then when you release to the general public most error should be covered..

I found an error by entering a password on start, then accidently saving a new password as nothing (never asked to confirm i want to change password etc), then getting locked out of the program with a wrong password message, as you coded the loading form not to accept nothing as a password....
= loop... lol..

Deleting "psdb.data" in app local, cleared up the issue. but its a pain.. also the passwords are not organised in any way , so after you build up a load you will have to search like fuck lol

But good otherwise. :)

Going to PM you for the source, I really want to check this out, and possibly improve it. I've been looking to start somewhere with encrypting, and I think this would be the best program to begin with!
Thank you in advance!
