Thread: [Wifi Pineapple from Hak5. Modules don't work?](#)

Malagant_2 - July 24, 2013, 4:21 pm

So I bought a device called the wifi pineapple from a company and show called Hak5 if you're familiar with it.

I'm having so many difficulties with the modules that you can install into the pineapple. They simply won't work the way they should and I don't know how to view the log files it saves onto the USB hooked into the pineapple.

Wouldn't it be easier to just use commands on the eth0 itself rather than hassling with the modules?

There is only one problem with that. When I go to do simple commands such as "urlsnarf -i eth0" it doesn't show any live browsing even when I am browsing websites on the pineapple's internet.

I just don't get it.

I know I might be asking for a bit much from the community here but I would really appreciate if someone could tell me how to either get these modules working or better yet, tell me why ettercap commands and urlsnarf commands (commands like that) are not working on the eth0 connection when clearly there are people using my pineapple device.

Otherwise I wasted \$100 on this pineapple device if I can't get it to show me live website browsing and do MITM properly. This shouldn't be this hard.

I tried posting on the pineapple forums, but nobody there has offered any useful solutions that are simple enough to understand.

I think I figured out what was going on when I was trying to do commands for my pineapple in the terminal. It won't show anything if I do anything on the network, only when foreign devices connect and do things.

I don't think pineapples have any electronics. You could try eating it for the most satisfaction.

Malagant_2 - July 24, 2013, 5:59 pm

lol. No. Google hak5 shop and you'll see what I'm talking about. Good one though XD

I Googled pineapple and I am still pretty sure, I would not recommend plugging in anything.

Malagant_2 - July 24, 2013, 7:21 pm

The USB is for installing modules but the guy who designed the modules for this device did poorly. You have an issue with almost all of the modules you can install. Its better that someone just uses the konsole for performing tasks on the pineapple instead of letting a module do all the work.

What is with you and pineapples? Have you tried an apple?

Wifi Apples are total shit. Wifi melon is okay. The best by far is wifi durian.

Durian:

I'm pretty sure you need to become mitm before anything spectacular can happen. It's easy with WiPi :)
