Thread: [CPU Temp](#)

Moon Rock - August 24, 2013, 11:13 am

I've been putting codes together to make a TaskManager so far it has processes and process kill CPU + RAM Usage, but I want to add a temperature label. I've tried different codes, but there not working. I heard you have to run it in Win Xp I did but still nothing I want to make it a label that refreshes in a timer, so can anyone tell/link me something that can help me thanks for using your time to read this.

Code Function GetTemp() As String

Try

Dim searcher As New ManagementObjectSearcher("root\WMI", "SELECT * FROM MSAcpi_ThermalZoneTemperature")

For Each queryObj As ManagementObject In searcher.Get()

Dim temp As Double = CDbI(queryObj("CurrentTemperature"))

temp = (temp - 2732) / 10.0

return temp.toString()

Next

Catch ex As ManagementException

MessageBox.Show(ex.Message)

return nothing

End Try

End Function
