Thread: [How to shut down a site](#)

Hellblood - October 13, 2014, 9:22 am

any tutorial or something like that also i need to know some safe measurements to do that
Thanks

Bob White - October 13, 2014, 9:23 am

What do you mean shut down? Do you want to attack it so it stays offline, do you want to hack it, do you want to deface it?

Hellblood - October 13, 2014, 9:25 am

I want to shut down it , no hack no deface like shutting down the hosting ddos attack something like that

Sucker for pain - October 13, 2014, 9:26 am

yeah, ddos its ass, or just purchase a website downie service ;)

Hunting Rifle - October 13, 2014, 9:26 am

PM me with more info, I could do this for you.

Well, depending on the host, you can surf over to the Server Stress Testing section and purchase a stresser. Most have both layer 4 and layer 7 attack methods.

I would suggest buying vdos. It's the best stresser on the market right now.

Layer 4 is gonna need the websites IP address, which you can easily resolve using any domain to ip site like [THIS](#) one for example.

If the website has cloudflare, you may need to resolve that cloudflare so you can get the real IP address.

After you get that sorted, you should either attack their IP address with a layer 4 attack, or attack their domain (<http://www.website.com>) with a layer 7 attack.

If you need more help, feel free to ask!
