Thread: [\["HQ"-Tut\] Find the real I.P. behind a Cloudflare protected server](#)

Dr. Lightman - July 30, 2016, 12:12 pm

Hey,

So it's simple, from my personal experience. Let's say this is a Minecraft community, it has basically three things ; A website, a teamspeak, a Minecraft server application.

To make this tutorial more realistic lets take exemple with this Minecraft website : <https://forum.aliacraft.net/> I did check, no vulnerabilities that would leak the domain I.P., at least not with the last tutorials I found here on HF.

Now, what's interesting is their Teamspeak server, if they have their own Dedi/vps they'll most likely host it on the same server right ? Then, just check for the subdomain. Here it's : voice.aliacraft.net . It points out the an OVH Server. Amazing, now lets check if it's the same as for the Website server, go to : <http://167.114.21.xx> (TS3's IP). It leads to the Website, we won.

Basically if there's no TS3, use this method with the minecraft(Or any game server) domain, or any else application.

This won't help you in all situation, but in some fields it will help you, especially when all others cloudflare 'resolvers' didn't work.

2nd way : Check for the domain history, and check previous hosters before Cloudflare. If there's OVH, or any other hoster, then check the IP to see where it leads to. If it leads to the website, then you got the back-end IP

Here is the website for this : <http://viewdns.info/iphistory/>
