Thread: [\[Release\] MailTool v.1.2 - Spoof, Mass, Bomb Email - Works on Windows and Linux.](#)

Malicious Intent - November 23, 2016, 10:37 pm

Mail Tool v1.2

Email Tool works on Windows and Linux via Wine - I generated EXE file since some people have problem installing Python environment.

This tool is standalone and doesn't require you to have Python anymore. Uses Gmail SMTP, supports attachments and HTML. Make sure to enable access for less secure apps (Gmail will not allow for tampering with email headers if SSL in use so I had to resort to TLS). Custom SMTP available in full version.

To use HTML template simply provide the name of the file (e.g template.html) if in the same directory or the full path, if its located else where on your drive. Same goes for Mailing List. You can use a name, email address or both in Spoofed email address box. The size of the file is big because it contains python environment required for its operation(~4mb). I might add a list of known SMS gateway for those who don't know how to Google.

This tool is tested on Linux and Windows 10 VM. Should work on other versions too.

Decided to stick with the Console as opposed to GUI to maintain the versatility.
Enjoy.

Known limits

Gmail will only allow ~100 emails sent at once.

Gmail will only allow ~400 emails sent per day per account.

Above limits are only for Gmail(If you use full version you can setup different SMTP)

Functions

Send Spoofed Email

Send Email bomb (anti-stacking)

Mass Mail aka Phishing campaign

Spoof Email

Allows for sending a single spoofed email.

Mail Bomb (anti-stacking)

Supports anti-stacking by adding random string to the subject line.

It can be used as a SMS bomber if you know how to send email->sms.

(Works with American Carriers, didn't test with any others. Note: The list of the sms gateaways can be found online.)

Mass Email (Mailing list support)

This function supports mailing list (e.g txt file). Allows for sending the same email to many addresses at once.

Useful for phishing or marketing campaigns.

Download

Spoiler ([Click to View](https://ufile.io/85233))<https://ufile.io/85233>

Scan

Note there are some false positives on VT because pyinstaller was used to create EXE file.

Pyinstaller is used by frameworks like Metasploit and Veil Evasion for malware hence the false positives. Run in VM if you don't trust the file.

Spoiler ([Click to View](#))

Custom version available, includes custom smtp settings and couple of other improvements.

This version is free, my time isn't, so please don't message me unless you want to pay.

Also I take no responsibility for how you use this tool.

It's designed to help pentesters, marketers and security researchers.

?V?T?R - November 23, 2016, 10:39 pm

Thanks for this, I'm planning to use this pretty soon.

Can you Pm Me Thanks a lot.

Malicious Intent - February 26, 2017, 1:01 pm

This is old version that doesnt work correctly anymore due to some gmail shenanigans. If you need a updated version just let me know ..

force123 - February 27, 2017, 11:31 am

It works for all providers?

Malicious Intent - February 27, 2017, 11:38 am

Can make for all providers...

Hopsin - March 1, 2017, 3:15 am

(Nov 23, 2016 11:37 PM)Malicious Intent Wrote: [\[CITE\]](#) Free Email Bomber and Spoofer

The tool is written in Python 2.7 so you will need it in order to run it. It offers the same functionality as commercially available solutions offered here on HF. It's simple to use and gets the job done. All you need is Gmail account and since the tool doesn't support SSL yet you will have to enable login with less secure apps (refer to google search if you don't know how to do it). Tool is offered as is and i claim no responsibility for what you will do with it. I'm sure many of you could write it better but hey I'm offering it for free and it's still a learning process for me. I'm open to the criticism and suggestions. If you would like to see more features just comment below and i might implement them in future. Thinking of making GUI for it but for now you gotta use it in CMD/CLI. I made it coz the one I bought changed the owner and I was unable to login to it. Also my old bomber was for Windows only and my primary OS is Linux so i thought it would be cool to have a working solution for it.

If your Python installation is not full, you will need to install couple of modules:
pip install yagmail - script verifys if you have it so you can just run it for the instructions.
pip install pywin32 - it's only needed if run on windows.
pip install colorama - for colors to work.

Spoiler [\(Click to View\)](#)

It supports HTML and ATTACHMENTS. In Windows cmd you can't use keyboard shortcodes so no ctrl+v (means you have to type in the email manually or use cmd options to paste it). In Linux just use ctrl+shift+v.

I plan on adding features like:Multiple accounts support - to make sure victim cant block the attack.
(using login-pass.txt file as an input)

Random Email address, subject and body.

Mass Mail support to blast multiple email addresses at the same time.

GUI

SSL

Custom SMPT settings.

Download:
being updated

And what was the two processes it opened? Read what i said in OP about false positives then go to reverse.it and do the analysis. There is nothing strange with multiple processes starting. Its a python code converted to exe. It means that the python environment is being loaded at the same time.

Py installer is detected left and right but that is still the best way to convert py files to exe. The only reason i did convert it to exe is because people had probem installing python correctly. If you don't want to, you dont have to use it or simply run it in virtual machine. And unless you can provide the actual proof, dont accuse me of infecting the file.

System calls its making are 'cls' to clear the cmd. This is listed in hybrid analysis for some stupid reason.. Open your cmd and type 'cls'. - hacked lol

Make a following file and convert it to exe using pyinstaller:

```
Code import sys, os
```

```
def stupid():  
    print 'Malware'  
    os.system('cls')  
    os.system('cls')  
    os.system('cls')
```

```
stupid()  
sys.exit()
```

Now convert it with Code pyinstaller --onefile --console nameofyourfile.py And scan the output exe on VT or reverse.it .

Here is the link to the scan of above example. -

<https://www.reverse.it/sample/af89670dbf7aa19e07f82048d595fbecf09d0f697c6e841e8d98b23ffa8f9445?environmentId=100>

Feel free to do it yourself and see what happens.
