I was thinking about working on a project with a friend that:

- indexes every known popular CMS(joomla, wordpress, kayoko, osticket, drupal, vb, ipb, etc) specifically it attempts to index as many sites running these as possible including the domain name and the type of CMS it runs.
- indexes all directories on each of them and their plugins
- attempts to get all their admin directories via directory bruteforce
- There will be a common plugin area that will list the most common plugins between sites.

This would be a super useful resource for recon before messing with a site and auditing it. If you guys have any other ideas for this let me know below. This would be more effective than google dorks because google does not index everything.

Pretty much like the shodan for web apps, shodan usually only indexes services binded to ports.
