Thread: [Decompiling executable into source code](#)

TYLER - March 29, 2018, 1:37 am

Hello,

First and foremost, I apologize if this is the wrong section. Feel free to report this thread to be moved to the correct section if needed.

Anyway, I am working on a project and looking to decompile my .exe into its source code. I tried JetBrains dotPeek and pulls what I am looking for, however when exporting it to a project, it imports compiler generated code into source code if that makes sense. I know what I am looking at when opened in Visual Studio so when I build the source, it returns a bunch of errors in which I found out it's compiler generated code that is causing the errors. So if I can just simply export the project without the extra codes being included, then I have what I need. I am not doing anything for malicious or illegal intent, this is all purely a project I am working on.

Does anyone know how I can go about doing this?

Thanks!

In 99.9% of the cases you can remove the compiler generated code.

I recommend you to use either [DNSpy](#) which is the best or [Telerik JustDecompile](#).

If you send me the executable I will put it in a project for you

JustDecompile is discontinued, why would you use that? JetBrains DotPeek works really well for newer language versions too. DnSpy for it's other debugging and assembly modification features.

I am still getting updates for JustDecompile.

DotPeek is great but not the best.

True, DnSpy is great for debugging, but I am so used to it that I am using it for everything on daily basis.

Respect 0xDEAD10CC ?

Hmm, so I had to check my devcraft complete subscription for the downloads and I think I might've got mixed up with JustCode/JustTrace (discontinued) and JustDecompile which seems to be alive still.
