Thread: [Attempting to demonstrate CVE-2010-0425 \(mod_isapi module exploit\)](#)

ren11234 - October 15, 2019, 4:14 pm

I have a very basic understanding of this vulnerability and i am trying to demonstrate it for school, i currently have a Windows Server 2008 VM with Apache 2.2.8 running on it. My Kali VM is on the same network and i am able to see the http server running on port 80 with an nmap scan. i have the Apache mod_isapi dangling pointer metasploit module and it appears to be working correctly but i do not notice any change in my Apache Server. the Youtube video on the exploit allows the attacker to get root access through telnet but other sources say that the exploit results in a crash or DOS for the web server.

I dont really know what im doing but i feel like im close, can anyone point me in the right direction? im trying to get similar results to this youtube video although im on kali and it looks like hes on a windows machine

[/watch?v=kKRz_KhQXnI](#) (cant post links because i just made an account here, the vid is only 2 min)

considering that particular metasploit module is auxiliary, i'd be really fucking surprised if it popped a shell
