Thread: [Using Console App Code in Windows Forms?](#)

District - August 29, 2020, 3:34 am

I am making a trainer for the game Assault Cube as it is my first real C# project. Using VAMemory I can read and write the memory addresses to change stuff like health/ammo. I want to use this code in my Windows Form so that it'll modify the addresses on a button click event.

Check the picture in my spoiler for a possibly better explanation.

Spoiler [\(Click to View\)](#)

Apparently I need to pass vam to Form1.cs or subscribe to the events in Program.cs, but I have absolutely no idea how to do either or even understand why this needs to be done. Searching the docs helped me a little but I'm still really stuck... :(

Are you trying to do some design pattern?? if not then just copy the code from main and put it on the button accordingly..

No design pattern. I just really want to learn how to do it. I tried moving the code from main into the form and it just gave me a bunch of other problems.
