Thread: [Help: How change code to make undetected](#)

edurne - September 6, 2020, 9:53 am

Dear community, I need your help:

I have created an application, which is not a malware: it just allows to share your live PC screen with your friends.

So you click on the button and send the live Screen URL to your friends. They will be able to see the live screen of your computer on their browsers.

By hitting the button again, the screen sharing stops:

<https://www.wolfeye.us/share-your-screen.html>

My problem is: when you analyse that program on virustotal, you got 18 of 65 engines that say it is malware. So this is definitely a false positiv:

<https://www.virustotal.com/gui/file/ce4c0d7f4a69fa956097655f691936028dd31ed80c38550fff0c9292c5b31033/detection>

I have already started to contact them and submit th false positiv.

But I have a question to the specialists here:

What would I have to adjust to the source code to make the application undetected?

I hope you can help.

Thanks and Regards

E
