Thread: [How to use CryptUnprotectData \(win32\)](#)

lab232 - January 24, 2021, 7:15 am

I've been trying to make a simple password grabber (for educational purposes) that decrypts the text in the login data file stored by chrome. I can't find any coherent documentation on how to use this, so can someone lend me a hand?

xoxallfather - February 7, 2021, 10:31 am

It depends on what programming language you use. The "CryptUnprotectData" is a core windows API call. If you are using C you can easily import the particular lib (dpapi) that supports the codebase and start using it. You can easily find the MSDN documentation from Microsoft related to the function (just type "cryptunprotectdata msdn" in a browser).

Personally, I suggest using python cause it is noob friendly and you can find example codes in Github.

Sorry, the forums don't let me post links atm cause my account is new here.

Hope this will help you.

MSDN is your friend

<https://docs.microsoft.com/en-us/windows/win32/api/dpapi/nf-dpapi-cryptunprotectdata>
