Thread: [Adding string after int](#)

Will Patterson - August 31, 2021, 8:16 am

```
Code age = 22
daysalive = (age * 365)
print("Hello, you have been alive for" , daysalive +" days")
```

How would I format the print so it does not give errors?:

Traceback (most recent call last):

```
File "C:\Users\17275\Desktop\Python\daysAlive.py", line 3, in <module>
    print("Hello, you have been alive for" , daysalive +" days")
TypeError: unsupported operand type(s) for +: 'int' and 'str'
```

Thanks :)

the craavce - August 31, 2021, 8:37 am

```
age = 22
daysalive = (age 365)
print("Hello, you have been alive for " + str(daysalive)+ " days")
```

or

```
age = 22
daysalive = (age 365)
print("Hello, you have been alive for " , daysalive , " days")
```

just replace + with ,

daysalive = (age * 365)
print("Hello, you have been alive for " , daysalive , " days")
```

just replace + with ,
better would be

PHP Code

```
<?php
age = 22
daysalive = (age * 365)
print(f"Hello, you have been alive for {daysalive} days")
```

LEGION - September 7, 2021, 12:08 am

PHP Code

```
<?php
age = 22
daysalive = (age * 365)
print(f"Hello, you have been alive for {daysalive} days")
```

Even better would be

Code from datetime import date

```
birthday = date(1998, 12, 31)
delta = date.today() - birthday
print(f"Hello, you have been alive for {delta.days} days")
```

Code from datetime import date

```
birthday = date(1998, 12, 31)
delta = date.today() - birthday
print(f"Hello, you have been alive for {delta.days} days")
This isn't just better its the only correct answer per pep 498.
```
