VisualSploit - Poison Visual Studio Projects

Thought I'd pop back in to share an old project of mine which I never released. It's an interesting tool which utilizes VS projects on build events to execute a remote payload given powershell code injected to a VS project file. Hope you guys enjoy!

Download Source Code: <https://github.com/Meltedd/VisualSploit>

Features:

- Poison vbproj/csproj file by injecting malicious code
- Poisoned file remote payload via direct download link
- Schtasks persistence
- Startup persistence
- Disable Windows Defender (in progress)
- Fake error message & demonstration

Usage:

- Build the project
- Execute VisualSploit.exe
- Enter the direct download link to a payload
- Select the vb/csproj file to poison
- Select which AV evasion/persistence options you'd like to enable
- Choose to customize a fake error message

* NOTE: Builder logs are just for show, you can disable the task delay in lines 168-218 of Form1.cs :)

Isnt this essentially the same as using build events when compiling? If so this is almost nothing new.
